(54) Title: SYSTEM AND METHOD FOR MATCHING USERS WITH ITEMS IN A NETWORK

(57) Abstract

A system and method of determining and using psychographic information to help better match user's interests with products and services. Psychographic information is information about an individual's personality. This information can be associated with an item to indicate what personality traits are more common among people who are, or are not, more likely to be interested in that item. The system supports two types of profiles: user profiles (216) and item profiles (214). A user profile (216) contains the psychographic information showing correspondence, or lack thereof, between a user and various personality traits. Similarly, an item profile (214) describes the personality traits of users who are interested, or are not interested, in that item. These profiles can be associated with confidence levels to show which traits are better known in the profiles.

SYSTEM AND METHOD FOR MATCHING USERS WITH ITEMS IN A NETWORK

BACKGROUND OF THE INVENTION

Field of Invention

5 This invention relates to the field of systems and methods for matching users and items. In particular, the invention relates to approaches to matching users and items using parameters describing users and items to distribute feedback information and allow for improved matches.

Description of the Related Art

10 Two particular prior techniques have been used to provide matching of users with items in online environments. The first is collaborative filtering. The second is text sensitive interest vectors. Each will be considered, followed by a summary of other approaches.

A. Collaborative Filtering

15 Collaborative filtering is perhaps the most widely used prior technique for matching users and items. For example, several web advertising companies such as Firefly and DoubleClick use variations of collaborative filtering to select advertising for users. Similarly, services such as Movie Critic, <<http://www.moviecritic.com/>>, use products such as Likeminds, from
20 Andromedia, San Francisco, California, <<http://www.andromedia.com/>>, to perform collaborative filtering.

 The basic operation of collaborative filtering is simple: users provide feedback about items, e.g. banner ads, books, movies, etc., either explicitly (Movie Critic ratings) or implicitly (click on ad). For each user, a set, or cluster,
25 of likeminded users for that user is identified.

 As an example, take Movie Critic, new users of the web site are asked to rate a number of movies explicitly before recommendations are provided. The movies the user, John Doe, is asked to rate are selected from the movies other

users have already rated. Thus, commonly watched movies may be presented initially, e.g. "Star Wars", rather than less watched movies. The user's ratings for that initial list of movies are collected. Once a sufficient number of ratings have been provided, the system then attempts to suggest other movies the user
5 may find interesting.

This is accomplished using Likeminds™, a software package that identifies a set of likeminded users of the service. Thus, John, who may have rated a number of science fiction movies highly will be placed in a set of likeminded users who have made similar selections. The weighting given to the
10 opinions of each user in the set of likeminded users is adjusted based on the degree of correspondence to John's ratings. Thus, for example a likeminded user whose ratings match John's exactly will be weighted most heavily. In contrast, a likeminded user with less overlap to John's ratings will be weighted less heavily.

15 The recommendations stem from other movies rated by these likeminded users. Thus, unless a particular movie has been rated by a likeminded user, a recommendation cannot be provided.

As a result, as the number of users and items increase, the ability of collaborative filtering approaches to make matches diminishes rapidly, even
20 with large amounts of feedback. Further, these approaches present particular difficulties for newly added items. For example, the system cannot provide recommendations to go see "Star Wars: The Phantom Menace" to John until several likeminded users who rate movies similarly to John rate the movie favorably. These limitations also impact the ability to effectively use
25 collaborative filtering for advertisement presentation as well as implicit site customization. Another limitation arises from the one directional nature of the process, e.g. given a new item it is not possible to determine which users would be interested in the item.

Yet another limitation is that the profile for the user is entirely
30 non-transferable to other environments as it is solely the set of likeminded users. For example, a user's Movie Critic profile cannot be used at another site.

Another limitation is that collaborative filtering is not easily applied to non-homogenous collections of items. Within homogenous collections of items such as books or music, the reasons people tend to like, or dislike, items tend to be relatively uniform. However, as the diversity of items increases, the
5 assumption becomes increasingly incapable of describing the reasons users are interested, or disinterested, in certain items.

B. Text Sensitive Interest Vectors

Another approach that is occasionally used to match users and items is a text sensitive interest vector. Such an approach is used in part by
10 SelectResponse™ from HNC Software, Inc., San Diego, California, an automated electronic mail response agent.

The basic idea behind text sensitive interest vectors is that words are slotted into bins. For example, bin #1 might be for words relating to love, e.g. "love", "like", "approve", etc. The user's "interest" is the string of words
15 provided to the software, e.g. an electronic mail message, a search query, etc. For example, if the string included the sentence: "I wanted to tell you how much I really like your web browser. Really would love to have a T-shirt". Then, the text sensitive interest vector would have a value of "2" in the first position because two words from bin #1 appear.

20 The string of words is slotted into the bins. Similarly, documents or descriptions of items are slotted into the bins, typically ahead of time. The user's interest is then matched against the items by comparison of the vectors. The most similar matching items will have similar text sensitive interest vectors.

The approach is limited in many respects. For example, it is only
25 capable of working with textual descriptions of interests and items. Thus, it is not useful when the user's interest is not expressed as a string of words. Further, the approach does not afford for the identification of a profile of the user and item. Thus, the user's interests are merely a transitory expression of the user's query rather than a description of the user's long term, or permanent, traits,
30 preferences, etc.

BRIEF DESCRIPTION OF THE FIGURES

Fig. 1 illustrates a system including one embodiment of the invention for matching users to items.

5 Fig. 2 illustrates processes for selecting and displaying matching items for users.

Fig. 3 illustrates configuration and initialization settings used according to one embodiment of the invention.

10 Fig. 4 illustrates one embodiment of a process for incrementally updating user and item profiles with the filtering engine.

Fig. 5 illustrates a web page supporting explicit feedback with the feedback bar and ratings for elements hidden.

Fig. 6 illustrates a web page supporting explicit feedback with the feedback bar hidden and the rating for an element visible.

15 Fig. 7 illustrates a web page supporting explicit feedback with the feedback bar visible and the ratings elements hidden.

Fig. 8 illustrates a feedback or rating bar according to one embodiment of the invention.

20 Fig. 9 illustrates a feedback or rating bar according to one embodiment of the invention.

SUMMARY OF THE INVENTION

The problem can be stated: how can a particular user be presented at least one item by a web site that the user is likely to find interesting. More specifically, the goal is to select at least one item, from the set of available
5 items, with a preference profile similar in nature to that of the user. Thus, users whose user profile indicates they are "extravagant", as opposed to "cost conscious", should be shown items having item profiles that indicate that "extravagant" users are interested in those items.

A system and method of determining and using psychographic
10 information to help better match user's interests with products and services is described. Psychographic information can be associated with an item to indicate what personality traits are more common among people who are, or are not, more likely to be interested in that item.

The system supports two types of profiles: user profiles and item
15 profiles. A user profile contains the psychographic information showing correspondence, or lack thereof, between a user and various personality traits. Similarly, an item profile describes the personality traits of users who are interested, or are not interested, in that item. These profiles can be associated with confidence levels to show which traits are better known in the profiles.

20 To help provide better initial matches, the system can be initialized with predefined profiles, confidence levels, and a set of predefined relationships between the psychographic parameters. The set of predefined relationships define how pairs of the psychographic parameters correlate. An example of a predefined profile may be helpful: an item such as an advertisement for
25 women's shoes might be initialized with a value of "-3" for the "female vs. male" trait, indicating the item is generally interesting to women. Further, the degree of confidence in that initialized value might be set moderately high.

To improve the accuracy of the profiles, users' interactions with the system can be tracked and incorporated back into the user and item profiles. As
30 needed, the system can independently access a user's profile to select an item

representing a best match between a specific user's interests, as expressed through his/her personality traits. The system can be used in electronic commerce to provide users with banner advertisements, initiate electronic commercial transactions, and provide suggestions of items that are more
5 interesting to the users.

Although the description of the invention is described in terms of finding matching items for a given user, the system can also be used to match items to users. This may be desirable to allow a company to identify users who would be interested in a new product for marketing, research, and/or other
10 purposes. For example, this could be used to send targeted electronic mail messages to users likely to purchase, or be interested in, particular items.

CLAIMS53

ABSTRACT72

A. Introduction

First, the problem to be solved, the terminology being used, and
5 advantages of embodiments of the invention will be described. Then, an
environment including an embodiment of the invention will be considered. Next
the process for matching users and items will be discussed. Then the detailed
implementation used by some embodiments of the system and method will be
discussed in greater detail. Finally, additional embodiments of the invention will
10 be considered.

B. Description of the Problem

There are a number of situations where it is desirable to help match
users with items. For example, electronic commerce vendors want to show users
the items they are most likely to be interested in so that the user is likely to
15 complete a purchase. Similarly, many web sites want to increase the
click-through rate on advertising by presenting advertising that the user will
find most interesting. In each of these situations, it is desirable to select items
that the user is likely to find interesting.

1. Terminology

20 Some terminology will be helpful in understanding the basic statement
of the problem.

a. Item

The term "item" refers to a piece of information that can be accessed
over a network such as the Internet, a local area network (LAN), an intranet, an
25 extranet, and/or some other type of network.

The item may be distinct from the physical object(s)/service(s) the item
may correspond to. For example, a bookstore might sell a particular book on

computer programming. The book is the physical object, but the item can be a banner ad for the book, a link to a description of book, a uniform resource indicator (URI) where more information about the book can be found, etc.

In another example, consider an advertisement for a Hawaiian vacation.

5 The item in this case might be the banner ad, the web page listing details of the vacation, etc. The corresponding service to this item would be the actual Hawaiian vacation.

A third example is that the physical object might be a digital item, e.g. a web page, a database entry, an online book, a multimedia content, and/or some
10 other type of digital object. The physical object might be an MP3 track, but the item could be the link to the MP3 track, a banner ad for the MP3 track, a link to a sample of the MP3 track, a link to complete a purchase of the MP3 track, and/or some other piece of information that can be accessed over a network.

In the interest of clarity of description, items will sometimes be referred
15 to by the physical object(s)/service(s) they correspond to. Thus, the phrase "Hawaiian vacation item" should be understood to correspond to the item, not the Hawaiian vacation itself.

b. User

The term "user" refers to an individual, or other entity acting on behalf
20 of another. For example, a user might correspond to a person, John Doe, sitting at his personal computer accessing an online bookstore. Alternatively, the user might correspond to an automated agent acting on John's behalf.

In the interest of clarity of description, users will sometimes be referred
to by the person(s)/agent(s) they correspond to. Thus, the phrase "John's user
25 profile" refers to information about John, not John himself. Similarly, "the user's profile" means the corresponding profile for a user.

Also, in some instances, a "user" may refer to a collection of individual
users being treated as a common entity. For example, in some embodiments of
the invention, all of the individual users in a single department, or other logical
30 group, might be treated as a single user for matching purposes.

c. Preference Profile

A "preference profile" contains psychographic information indicating a degree of correspondence, or lack thereof, between a user and various personality traits. The personality traits are descriptive phrases that can be used in psychography to systemically evaluate a individuals personality, e.g. behaviors, tendencies, tastes, interests, etc. Personality traits are distinct from demographic characteristics in that they do not necessarily correspond to factual information about an individual. For example, a user may be thirty years old, a demographic characteristic; however, his behaviors may indicate that he is more like an 18 to 22 year-old, a personality trait.

Particular personality traits can be described within a preference profile, according to some embodiments of the invention, using a number. For example, the personality trait "cost conscious vs. extravagant" could be one of the parameters stored in a preference profile. Numbers from "-3" to "3" could be used to indicate correspondence, or lack thereof, between the user and that trait. For example, a "3" might indicate the user is extravagant, while "-3" might indicate the user is highly cost conscious. Intermediate values, e.g. "1.1" would indicate a lesser degree of extravagance than a "3".

Additionally, preference profiles can have a confidence value associated with each profile parameter. These confidence values can be adjusted as more information is learned about users and items. In some embodiments, the preference profile parameters are stored together with a covariance matrix describing the degree of confidence in the parameters of the preference profile. A small covariance indicates a high degree of confidence in the value of a parameter and a large covariance indicates a low degree of confidence in the value of a parameter.

d. User Profile

A user profile is a preference profile for a user comprised of one or more parameter values for personality traits. Thus, if one of the parameters in the user profile is "cost conscious vs. extravagant", then the value of that parameter

would describe how cost conscious or extravagant the user is. Various embodiments of the invention may use different personality traits in the preference profile.

e. Item Profile

5 An item profile is a preference profile describing the personality traits of users that like the particular item. As such, the data structures used to store item profiles can be the same as those used for user profiles. The difference between user profiles and item profiles therefore lies in the meaning of the personality trait parameter values.

10 Consider an item corresponding to an expensive fountain pen. The item profile parameter values describe the personality traits of users who are interested in the item. Since the fountain pen item is an expensive, luxury item, one would expect that it would be most interesting to extravagant rather than cost conscious users. Thus, a "1.7" value for the "cost conscious vs.
15 extravagant" parameter in the item profile would indicate that users who have extravagant personality traits would be interested in the item.

f. Program

 The terms "program", or "computer program", as used in this application, refers to any sequence of instructions designed for execution on a
20 computer system. A program may include a subroutine, a function, a procedure, an object method, an object implementation, an executable application, an applet, a servlet, a source code, an object code, and/or some other sequence of instructions designed for execution on a computer system.

g. Interactions

25 The term "interaction" refers to any affirmative action by a user that is used to define a personality trait. For example, an interaction may comprise a user's request of a URI corresponding to an item, e.g. "Add 'Fodor's Hawaii 2000' to your shopping cart". As a result of this interaction, requesting that the

Fodor's Hawaii 2000 item be added to the user's shopping cart, both the user's profile and the item's profile can be updated. A full description of the interactions used by some embodiments of the invention is discussed below in connection with "Categories of Profile Events".

5 h. Well-conditioned

Conditioning refers to the insensitivity of an estimation process to imperfect information and/or noisy data. Thus, a well-conditioned estimation process will not produce bad estimates, even when there is a relatively large amount of noisy data. Since a user's interaction with an item can be influenced
10 by many unmodeled factors, the estimation of the user profile parameters, or item profile parameters, needs to be well-conditioned so as not to be unduly affected by the noisy data, e.g. the unmodeled factors. The larger the number of data sources used to estimate parameters, the more well-conditioned the estimate. The data sources used by some embodiments of the invention include
15 initialized values and settings, described below, and multiple, noisy measurements, representing interactions between items and users.

2. Statement of the Problem and Solution

Having defined the terminology, the problem can be stated: how can a particular user be presented with at least one item by a web site that the user is
20 likely to find interesting. More specifically, the goal is to select at least one item, from the set of available items, with a preference profile similar in nature to that of the user. Thus, users whose user profile indicates they are "extravagant", as opposed to "cost conscious", should be shown items having item profiles that indicate that "extravagant" users are interested in those items.

25 A system and method of determining and using psychographic information to help better match user's interests with products and services is described. Psychographic information can be associated with an item to indicate what personality traits are more common among people who are, or are not, more likely to be interested in that item.

The system supports two types of profiles: user profiles and item profiles. A user profile contains the psychographic information showing correspondence, or lack thereof, between a user and various personality traits. Similarly, an item profile describes the personality traits of users who are
5 interested, or are not interested, in that item. These profiles can be associated with confidence levels to show which traits are better known in the profiles.

To help provide better initial matches, the system can be initialized with predefined profiles, confidence levels, and a set of predefined relationships between the psychographic parameters. The set of predefined relationships
10 define how pairs of the psychographic parameters correlate. As an example of a predefined profile, an item such as an advertisement for women's shoes might be initialized with a value of "-3" for the "female vs. male" trait, indicating the item is generally interesting to women. Further, the degree of confidence in that initialized value might be set moderately high.

15 To improve the accuracy of the profiles, users' interactions with the system can be tracked and incorporated back into the user and item profiles. As needed, the system can independently access a user's profile to select an item representing a best match between a specific user's interests, as expressed through his/her personality traits. The system can be used in electronic
20 commerce to provide users with banner advertisements, initiate electronic commercial transactions, and provide suggestions of items that are more interesting to the users.

Also, although the description of the invention is described in terms of finding matching items for a given user, the system can also be used to match
25 items to users. This may be desirable to allow a company to identify users who would be interested in a new product for marketing, research, and/or other purposes. For example, this could be used to send targeted electronic mail messages to users likely to purchase, or be interested in, particular items.

Several advantages of embodiments of the invention will now be
30 described. Then, an environment including an embodiment of the invention will be described.

3. Estimation with Limited Data

In most environments where the matching system will be used, the number of items will be vast. For example, an online bookstore might have tens of thousands of books for sale. Similarly, a portal web site might have millions of items, e.g. banner ads and links, that could be shown to the user. One advantage of embodiments of the invention is that a well conditioned estimate of desirable matches can be produced with extremely limited data. This allows newly added items to quickly be matched to users without the need for extensive sampling. It also allows sites to quickly suggest items to newer users without the need for an extensive training period.

4. Independence of Profiles

Another advantage of embodiments of the invention is that the preference profile is independent of the particular set of items, or users. This characteristic is called transportability. An example may be helpful in understanding this. Consider our user John Doe discussed above. The preference profile for John at a first web site, e.g.

<<http://www.example1.com/>>, can be used at a second web site, e.g.

<<http://www.example2.com/>>.

For example, on the first site, he purchases a book titled "Seeing Hawaii in Style". His profile is then updated by the first site. When, the user visits the second web site, a travel site for example, more luxurious travel experiences such as a "Luxury Hawaiian Cruise" could be recommended using the transported user profile from the first web site.

This transportability of item, and user, preference profiles, even across sites, increases the flexibility of the system and allows for greater cross-site collaboration.

5. Rapid Adaptation of System

The ability of the system and method to quickly hone in on the user's, or item's, profile also offers an advantage: it eliminates the need for explicit training of the system. As discussed above, embodiments of the invention can make well-conditioned estimates of what items a user will find interesting even with relatively little profile information for either the user or the item.

The adaptation of the user, and item, profiles can occur quickly because information about the correlation between parameters is used to adjust the user, and item, profile in response to interactions. For example, consider if two of the parameters that make up the preference profile are "age (infant)" and "uneducated vs. educated". It may be known, or determined statistically, that those two parameters are inversely correlated, e.g. users who have a strong rating in the infant trait, "3", tend to be relatively uneducated, "-3". Thus, information about a user, or item, in one profile parameter can be used to enforce consistency in the values of other profile parameters.

Further, values for items can be seeded to further assist the process. This can be done by identifying one or more sets of similar objects, e.g. vacations, clothing, women's clothing, etc. Items within a set can be provided default values for certain profile parameters based on settings for the set. For example, it may be known that items in the set of women's clothing are mostly interesting to user's whose user profile indicates that they have expressed a high degree of female-ness, e.g. "-2.7" in "female vs. male" personality trait. Thus new women's clothing items can easily be initialized using the set default profile value for the "female vs. male" attribute.

In some embodiments, the sets are formalized by using one or more categorization systems for products and services. In these embodiments, it may be possible to determine the appropriate category for items using standard references and/or information provided by vendors. This can reduce the overhead associated with the editorial process of identifying sets, and placing items into sets, manually.

6. Use of Confidence Bounds In Embodiments of the Invention

Another advantage of embodiments of the invention is that information about how well the system knows various types of information is also maintained. Returning to the example of the Hawaiian vacation item initialized
5 based on values for a vacation category, the confidence bounds could initially be configured to be low, allowing for rapid adjustment of the preference profile of the item in response to feedback. In contrast, as more feedback is received about a particular item, or user, the confidence in the preference profile will typically become higher. The confidence bounds enable more efficient transfer
10 of information from the user profile to the item profile, or vice-versa, as a result of interactions.

7. Ability of Preference Profile to Describe Items and Users

The preference profile used by embodiments of the invention offers an advantage in that the same profile can be used to describe items and users. More
15 specifically, the parameters associated with users and items are typically identical. In some instances the user profile may include more parameters than the item profile, such as when a user profile from one web site is used at another web site using fewer preference profile parameters to describe items. In this case, a mapping is performed between the parameters of the user profile from
20 the first web site onto the parameters used by the second web site.

C. System Overview

Figure 1 illustrates a system including one embodiment of the invention for matching users to items. The system can support the matching of users with items according the method described above. This environment could be used
25 by an electronic commerce vendor to provide product suggestions, banner ad selection, category suggestions, and/or suggestion or selection of other items for users.

The following paragraph describes the elements of Figure 1 and their interconnections. Figure 1 includes a web browser 100, a network 102, a server environment 104, and a profiling and matching environment 112. The server environment 104 includes a web server 106, a web site files 108, and an item database 110. The profiling and matching environment 112 includes a filtering engine 114, a matching engine 116, a profile database 118, and a settings 120. The web browser 100, the server environment 104, and the profiling and matching environment 112 are coupled in communication with the network 102.

The web browser 100 can include any computer, or other similar web enabled device. Similarly, the web browser 100 could comprise a handheld - or other - wireless communication device accessing the server environment 104 over a wireless network. For example, embodiments of the invention could be used with a PCS telephone to display advertisements, products for sale, shops of interest, locations of interest, or other items of interest, on the telephone display, or by voice, based on the user profile associated with the PCS telephone. Additionally, a voice activated response (VAR) system could employ embodiments of the invention. In those embodiments, the web browser 100 comprises a telephone providing speech and/or dual-tone multi-frequency (DTMF) inputs to the VAR. In such an embodiment of the invention, the VAR - or human operator -- could recommend items to the calling user based on the user profile and the matching process.

Although the discussion will concentrate on embodiments of the invention that operate over the Internet using the World Wide Web, in fact, this system and method can be used in other environments where it is desirable to match users with items. For example, a database search system could use this approach to assist in finding records, e.g. items, most likely to be of interest to the user.

The network 102 is a network such as a packet switched network, a wireless network, the Internet, an intranet, an extranet, a virtual private network, and/or some other communication medium for coupling the web browser 100, the server environment 104, and the profiling and matching environment 112 in

communication. In some embodiments of the invention, the profiling and matching environment 112 is coupled to the server environment 104 by a second network other than the network 102, e.g. an internal network, a direct connection, and/or some other communication channel.

5 The server environment 104 and the profiling and matching environment 112 can be located at the same site, or separately located. For example, the profiling and matching environment 112 might be operated by a company that works with a number of different web sites, including the one corresponding to the server environment 104.

10 The server environment 104 includes one or more computer systems operating the web server 106. The web server 106 can provide access to the web site files 108 using a hypertext transfer protocol (HTTP), as well as other protocols, e.g. file transfer protocol (FTP), electronic mail (standard mail transport protocol/SMTP), and/or database queries (standard query
15 language/SQL, open database connectivity standard/ODBC, Java™ database connectivity standard/JDBC, etc.). Similarly, the contents of the item database 110 may be similarly accessed. The item database is located within the server environment 104 in this example, but it could also be located within the profiling and matching environment 112, or shared between the two
20 environments.

 The one or more computer systems supporting the server environment 104 are typically server computers operating with the Windows™ NT operating system and/or a UNIX™-style operating system; although, any type of computer system supporting appropriate access protocols for the web browser
25 100 over the network 102 can be used.

 The web site files 108 are the basic content of the web site provided by the server environment 104. This may include applets, servlets, common gateway interface (CGI) programs, logos, artwork, hypertext markup language (HTML) files, and/or other content. The item database 110 includes the
30 changing content, e.g. descriptions of physical objects for sale, services for sale, banner ads, multimedia files for browsing and/or purchase, database records,

etc. Thus, the difference between the web site files 108 and the items in the item database 110 is that no item profile is associated with the web site files 108.

To be clear, the item database 110 cannot, for obvious reasons, store the actual Hawaiian vacation item or the physical object of a hardcover book on
5 computer programming. For these types of items, descriptions and/or appropriate purchase links are provided. In contrast, for digital goods, e.g. multimedia files, database records, and the like, the item database 110 may contain the digital good, or a reference to it. In some embodiments, the server environment 104 may also include a user database. The user database could
10 contain specific information about users, e.g. their registration information, their site specific information, their customized start page, etc. Like the item database 110, the user database might be located in the filtering and matching environment 112.

The settings 120 are used to configure the other elements of the profiling
15 and matching environment 112. A greater discussion of the settings 120 is described below. The profile database 118 can be a database, or other storage repository, for user profiles and item profiles. In some embodiments, the profile database 118 may be comprised of separate databases for user profiles and item profiles. Some embodiments of the invention may include caching of user and
20 item profiles in the profile database 118. Additionally, the profile database 118 and/or the settings 120 can be located within the server environment 104.

The filtering engine 114 receives interaction information from the server environment 104, or the web browser 100 when appropriate, to adjust user profiles and item profiles based on the interactions. In some embodiments of the
25 invention, the interaction data is stored within the server environment 104. This interaction data can then be periodically accessed by the profiling and matching environment 112 to perform incremental profile updates and to perform global profile updates.

The matching engine 116 responds to requests from the server
30 environment 104 to select one or more items for a user. The matching engine 116 accesses the profile database 118 to obtain the appropriate user profile and

select a matching item that is likely to interest the user based on the item profiles.

Notably, the filtering engine 114 and the matching engine 116 can operate independently. As such, interactions can continuously be used to adjust user profiles and item profiles independently of the process of providing matching items.

The matching engine 116 and the filtering engine 114 can be supported on one or more computer systems. The matching engine 116 and the filtering engine 114 can be one or more programs executing on one or more computer systems.

Several applications of various embodiments of the invention will now be described with reference to Figure 1. Then, the filtering and matching processes used by the filtering engine 114 and the matching engine 116 will be described in greater detail.

1. Banner Advertisement

One use for embodiments of the invention is the selection of banner, or other, advertisements for display in conjunction with the content from the web site files 108. When appropriate, a single profiling and matching environment with the banner advertisements can be used to support multiple server environments 104 operated by the same, or different, site operators.

In this embodiment, the item database 110 would contain the banner advertisements, or references to them. In some embodiments, the banner advertisements may be stored within the profiling and matching environment 112 instead of the server environment 104.

In some embodiments, the web server 106 could query the profiling and matching environment 112 to request the advertisement. Alternatively, an appropriate URI can be included in the file sent to the web browser 100 to cause the web browser 100 to request a matching advertisement. For example, the file sent to the browser might include:

This embedded URI could cause the web browser 100 to access a web server to retrieve an advertisement. Cookies, additional values in the URI such as a user identifier, and/or other approaches, can be used to allow the profiling and matching environment 112 to identify the user and/or the originating server environment 104.

The banner advertisement configuration can co-exist with the use of embodiments of the invention described below. For example, an electronic commerce vendor could use an embodiment of the invention to recommend books while at the same time the company that provides the bookstore's advertisements could use an embodiment of the invention to select advertising. In these situations, a common user profile can be used across the different sites when desirable.

2. Merchandising for Electronic Commerce Vendor

One extremely valuable use for embodiments of the invention is the recommendation, or suggestion, of items that the user may be interested in purchasing. This may take the form of displaying one or more suggestions to the user of the electronic commerce vendor's web site, the adjustment of the order of listing of items within a category at the web site, and/or other activities.

Consider a few practical uses of these embodiments of the invention. When a user goes to the vendor's home page, the items shown -- as well as the advertisements -- may be selected using the user's profile to select those items with profiles that most closely match the user. Thus, users whose profile indicates that they are cost conscious will be shown items that have profiles indicating the item appeals to cost conscious users.

Typically this procedure uses the matching technique to provide items of interest to fill in a template describing the layout of information in a web page. For example, on a single page, a vendor's template may indicate the placement of paid advertising in various locations, featured items in other locations, a "other categories of interest" list in another location, and one or more items in still another location. Each of those template components may, when

appropriate, be selected by using embodiments of the invention to select items of interest. Continuing the example, the featured items might be selected based on the user profile, while a list of items might be the search results.

Another use is to arrange the order of items within a list. For example,
5 the list might be generated in response to a search query. In other situations, the list might be generated by a request for items within a particular site-based category. For example, items the user is likely to have a stronger psychographic affinity for can be placed earlier in the list.

Still other uses are possible. For example, the site navigation categories
10 could be arranged to match the user's psychographic profile and the corresponding item profile for the category.

3. Web Portal

Another use of embodiments of the invention is in the automatic
customization of portal -- or other -- sites. Two main types of automatic
15 customizations will be considered in turn.

Within individual categories of a portal site, some embodiments of the invention can customize the content, ordering, and/or presentation of items within the category. For example, within a category of news headlines, an embodiment of the invention could rank and select the headlines likely to be of
20 most interest according to the user's profile.

Some embodiments of the invention may reorganize the presentation of a site based on the user's profile, such as selecting a predetermined number of site-based categories to display as part of the initial page. For example, consider a user whose psychographic profile indicates that her/his strongest interests lie
25 in outdoor sports. The automatically customized initial page may include the "Outdoor Sports" category for display to the user. Consequently, the user would not have to browse through the standard site hierarchy, e.g. "Recreation", then "Sports", then "Outdoors", to reach her/his category of interest. This process can be repeated within given categories as well as at the main customized page
30 for the user.

This allows for a tremendous amount of customization of the portal site without the need for explicit configuration of the page for the user. Further, as the user performs manual customizations, the user and item profiles could be further updated.

5 4. On the Street Personalization

Several embodiments of the invention support the use of wireless computers and/or telephones to provide access to customized information. The telephone may be either cellular, landline, and/or some other type of telephone. For example, using a wireless computer and/or telephone, a user could access a
10 server environment (e.g. the server environment 104) that provides recommendations for a particular topic or topics using a profiling and matching environment (e.g. the profiling and matching environment 114). In each of the following examples, if desired, the system can perform an initial selection set of items based on objective criteria, e.g. driving distance, location, etc., and then
15 use profiles to select the best match within the remaining items. The result: the user is provided with items most likely to match her/his interests. The set of items considered for matching can be limited to an appropriate scope, e.g. nearby, within the greater Los Angeles area, in stock at the particular brick-and-mortar store, etc.

20 For example, while a user is traveling, she/he could query the system using her/his wireless computer and/or telephone to contact the server environment 104. Then, the site could employ embodiments of the invention to select travel sites, e.g. items, most likely to interest the user based on the profiles for the travel sites and the user profile. For example, in Los Angeles, a
25 trendy and extravagant user might be recommended to Rodeo Drive. The particular set of travel sites is determined by the contents of the item database as selected by the server environment.

Similarly, embodiments of the invention can be used as an intelligent
yellow pages. From her/his handheld computer and/or telephone, either wireless
30 or landline, the user could request a restaurant. Rather than selecting the closest

restaurant, or selecting restaurants based on categories, the restaurant can be chosen by using the user profile and restaurant, item, profiles.

Another, "on the street" embodiment is in assisting customers in a brick-and-mortar store. For example, a user may use her/his wireless computer and/or telephone to provide feedback about particular merchandise. This allows on-the-fly cross-selling of related items as well as suggestions of other items the user may find interesting.

Now the processes used by embodiments of the invention to show and select content will be described. Then, the configuration and initialization of embodiments of the invention will be described. Finally, a detailed explanation of the processes follows.

D. Process Overviews

Figure 2 illustrates processes for selecting and displaying matching items for users. These processes can be used by the filtering engine 114 and the matching engine 116 to update user and item profiles and select a matching item. Notably, the processes 230 and 232 can operate independently allowing updates and the selection and display of matching items to operate concurrently.

1. Updating User and Item Profiles

The process 230 is used to update user and item profiles in response to interactions. This process is typically performed by the filtering engine 114. First, at step 200, a record of interactions is received. This can be in the form of a web server access log, or other recorded record of user interactions. In some embodiments, the interaction information is provided directly to the profiling and matching environment 112 as interactions occur either from the server environment 104 or the web browser 100. Next, at step 204, the user profile and the item profile is updated and stored within the item profiles 214 or the user profiles 216 of the profile database 118. The update process is described in greater detail below. The process continues at step 200 and can be repeated as needed to adjust for additional interactions.

For example, if the user John Doe clicked on an item, corresponding to a computer programming book, to get more detail, that interaction might be used to adjust both the user profile for John and the item profile for the book item.

Note, in some embodiments of the invention, the interactions can be provided asynchronously to the system. For example, purchase history information can be provided as interactions to the system. For example, club card information about purchases can be input into the system. The purchase interactions would be applied to updating the corresponding user and item profiles.

10 2. Selecting and Displaying Matching Items

The process 232 is used to select and display matching items to the user. This process is typically performed by the matching engine 116. First, at step 220, a request for an item is received. The request may originate from the server environment 104 or the web browser 100. If necessary, the user is identified at this step. Typically, the request will include an identifier for the user. Alternatively, cookies stored with the web browser 100 and/or parameters in the uniform resource indicator (URI) requesting the item may be used to identify the user. If necessary, a new profile can be created or the user can be prompted to identify him/herself.

20 Next, at step 222, the corresponding user profile is accessed from the user profiles 216 in the profile database 118. That user profile is then matched against each of the item profiles in the item profiles 214 to identify the item having an item profile suggesting the user is likely to be interested in the item. Matching the item to the user is based upon the proximity of the item profile parameters to the user profile parameters.

25 In some embodiments of the invention, the matching procedure can also take into account the confidences in the user profile parameters and item profile parameters. Accordingly, parameters that are known with a lesser degree of confidence will be weighted less in computing the proximity between the item profile parameters and the user profile parameters. In other instances, when

30

taking confidence levels into account, the parameters are adjusted pessimistically -- for both users and items -- based on the level of confidence in those parameters. The pessimistic approximations of the parameters are then used in determining the proximity of the user profile parameters and item profile parameters.

5 The process continues at step 224 with the presentation of the item to the user, e.g. in a page shown by the web browser 100.

The configuration and initialization of embodiments of the invention will now be described. Then, a detailed description of the processes 230 and

10 232 will follow.

E. Configuration and Initialization

Figure 3 illustrates configuration and initialization settings used according to one embodiment of the invention. Each of the configuration and initialization settings shown in Figure 3 can be included in the settings 120.

15 Each of the different settings will be considered and discussed in turn.

1. List of Parameters

The list of parameters 302 is the list of personality traits used in the preference profiles. A listing of twenty-six parameters used as the list of parameters 302, according to some embodiments of the invention, is shown in

20 Table 1.

1. Gender (Male vs. Female)	2. Education (High vs. Low)
3. Age (baby)	4. Age (toddler)
5. Age (preadolescent)	6. Age (adolescent)
7. Age (teenager)	8. Age (college)
9. Age (young professional)	10. Age (professional)
11. Age (retired)	12. Income (high vs. low)
13. Whimsical vs. utilitarian	14. Handy vs. contemplative
15. Trendy vs. above that	16. Sheep vs. less sheep
17. Cultured vs. uncultured	18. Adrenaline/violent vs. calm/caring
19. Libidinous vs. square	20. Curious vs. Indifferent
21. Stingy vs. spendthrift	22. Sports vs. no sport
23. Family vs. single	24. Active vs. couch potato
25. Flashy vs. conservative	26. Techie vs. Fuzzy

Table 1

The specific list of parameters 302 can be customized on a per site basis. Thus, for example, a web site aimed at sports fans might include additional parameters for personality traits that are useful in further distinguishing different types of sports fans.

5 Some general criteria for selecting parameters for use in embodiments of the invention may be helpful. The first criterion is that the list of parameters 302 should be capable of meaningfully distinguishing items within a set of similar items. Thus, parameters that are duplicative of existing parameters are not helpful.

10 Consider the following potential personality trait for inclusion in the list of parameters: "World Traveler vs. Homebody". If within a set of similar items, e.g. vacations, the new trait is not any more useful than the existing "active vs. couch-potato" trait (as well as the others), the new trait should not be added. But, if the new personality trait would increase the ability to distinguish
15 between similar items within sets of similar items like vacations, adding the new personality trait to the list of parameters may make sense.

A second criterion for selecting personality traits for inclusion in the preference profiles is that, for at least some of the traits, it is possible to seed items with initialized values. For example, many items have a strong association

with one gender trait, as such, gender makes a good parameter because initial values can be filled in for many large classes of items. It is not necessary for every personality trait to be susceptible to initial seeding; however, a wide range of easily assigned personality traits makes it easy to provide quick estimations
5 for new items.

Another criterion is that the selected parameters should be relevant to purchasing practices. The list of those parameters can be statistically determined. Alternatively, accepted, or widely, used personality traits that are considered relevant to purchasing decisions can be used. In some instances,
10 demographic information can be used to seed some parameter types and values, e.g., the physical fact of being male generally has a strong correlation with the male personality trait.

Yet another criterion, in some embodiments, is that the personality traits in the list of parameters be human understandable. This may be necessary to
15 comply with certain privacy initiatives such as the P3P privacy standard (Sponsored by the World Wide Web Consortium, P3P (Platform for Privacy Preferences Project) is a framework for products and practices that will let World Wide Web users control the amount of personal information they share with Web sites.). In other environments, this may not be a concern. Similarly,
20 the actual profile for a user may have to be presentable in human understandable terms. For this reason, some embodiments use a scale from “-3” to “3” to describe a user's personality traits within the user profile. Additionally, the confidence information may also be displayed if appropriate, or necessary, in human understandable terms, e.g. “very confident”, “low confidence”, etc.,
25 describing a particular parameter value within in the user profile.

Different embodiments of the invention can use different parameters. As such, profiles created in with one list of parameters 302 can be converted, or translated, into a profile using a different list of parameters by describing a mapping between the two lists of parameters. For example, three personality
30 traits in the list of parameters could be mapped by a formula, e.g. a weighted average, to a single personality trait in another list of parameters.

2. Parameter Meanings

The parameter meanings 304 is a set of descriptions describing what is meant by each personality trait included in the list of parameters 302. This is important primarily to permit for editorial consistency in seeding values for new items. For example, if there is no agreement as to what the “family vs. single” personality trait parameter means, then it will not be possible to consistently assign new items appropriate values for that parameter. The parameter meanings may also be useful, or necessary, to comply with privacy standards to allow users to be able to understand their own profile in simple language.

The parameter meanings are not used by the filtering engine 114 or the matching engine 116. As such, commonly accepted, or dictionary definitions, of those terms may be used. For example, the parameter meaning for “sports vs. no sports” might be: “A high value indicates a personality trait corresponding to users who watch sports, while a low value indicates users who do not watch sports.”

3. User Information

The user information 306 includes information that is used to initialize a user profile. For example, the registration form for a portal web site may have asked a number of demographic questions of the user. That information can be used to seed the user profile and be stored in the user profiles 216. Thus, for example a twenty-six year old male might be given a high value in the “Gender” parameter and a high value in the “Age (young professional)” parameter. Similarly, low values could be provided for the other age parameters. The confidence associated with those initial settings could be made low to allow the system to adjust the values towards a more accurate setting derived from interactions.

Other sources of the user information 306 may include credit card purchases, e.g. combine the item profiles for several recently purchased items to initialize the user profile. Also, psychographic data from other sources may be integrated into the user profile as well. In both instances, the confidence values

can be appropriately set to allow the user profile to be adjusted based on interactions.

The addition of users with user information 306 is ongoing as new users are added to the system or initialized based on data.

5 4. Seeding Item Information

As noted above, items may be grouped into logical sets of similar items for the purpose of assigning initial values. Thus, a set of items relating to women's clothing might be created with initial values for the item profile of items falling into that set. Some embodiments of the invention use a taxonomy 10 308 to assist in this process. For example, the hierarchical United Nations Standard Products and Service Codes (UN/SPSC) may provide a convenient, standard taxonomy. A description of the UN/SPSC can be found at <<http://www.un-spsc.org/>>.

Using a standard taxonomy offers the advantage that many items may be 15 pre-categorized, eliminating the need for manual categorization or grouping of items into appropriate sets. This reduces the configuration and initialization hurdles to providing seeded item profiles 310 for categories within the taxonomy 308. Thus, when a taxonomy is used, the seeded profiles can be constructed on a per category basis, creating one seeded profile for one or more 20 categories within the taxonomy 308. A subcategory within a hierarchical taxonomy 308 can automatically use the seeded profile of its parent category when no seeded profile has been provided for the subcategory.

In many instances, a large percentage of items may be pre-categorized, e.g. have an assigned and known category within the taxonomy 308. In other 25 instances, it may be necessary to manually categorize items for placement within the taxonomy. Once placed, each item can adopt the seeded profile of its category, or ancestor categories. The placement of items within the taxonomy may be ongoing as new items are added.

An example may be illustrative. In this example, the UN/SPSC is 30 adopted as the taxonomy 308. An example category in the UN/SPSC is:

Live Plant and Animal Material, Accessories and Supplies Live animals Livestock Cattle

- 5 Because "cattle" is a subcategory of "live animals", if an item profile for the category of "live animals" is established it can be used for the "livestock" and "cattle" subcategories if no more specific seeded profiles are defined for those categories.

5. Categories of Profile Events

- 10 As noted above, many interactions occur with users interacting with the server environment 104, the items in the item database 110, and/or the profiling and matching environment. Most generally, an interaction might include any click -- or other input -- from a user received by the server environment 104 and/or the profiling and matching environment 112.

- 15 However, embodiments of the invention use a subset of the entire range of interactions to adjust the profile. These interactions can be divided into the categories of profile events 316.

- In one embodiment of the invention, four categories of profile events 316 are used: buy events, details events, customization events, and navigation
20 events. A buy event is an interaction where a user purchases an item. A detail event is an interaction where a user requests more information about an item.

- A customization event is an interaction where a user customizes a personalized page. For example, a "stock watch" customization would be an interaction where a user adds, or removes, a stock to/from her/his stock watch
25 list. A list of customization events used by one embodiment of the invention appears in Table 2.

baby info	cartoon	chat	city of day
column	communities	download	fortune
fri	game	horoscope	link
living tip	local event	lottery	mon

moon	movie list	news	notepad
promo	reference	reminder	sat
saved search	service	soap	sport
sports ticker	stock	stock watch	sun
thu	tide	tue	tv
video list	weather	wed	

Table 2

When embodiments of the invention are used in environments that do not support customization, the customization event category can be removed from the categories of profile events 316. Further, the specific events in the customization event category can be adjusted based on the customizations supported by the particular server environment 104.

A navigation event is an interaction where a user navigates within the server environment 104, e.g. a request for any web page. For example, for a web portal site, using an embodiment of the invention, might have a navigation event for each of the primary categories, e.g. the first n levels of the site hierarchy. In another example, an electronic commerce vendor might have a navigation event defined for each "department" at the virtual store. For example, if a vendor sold books, music, and computer software, each of those three broad navigation categories of the web site could be a navigation event.

The filtering engine 114 only updates user profiles and/or item profiles in response to interactions that are within the categories of profile events 318. Events in the buy and detail categories can be used to update both the user profile and the respective item profile. Typically, customization and navigation events may be associated with their own preference profile which is updated in response to interactions from users. These preference profiles are used to update the user in the same manner as an item profile is used to update the user in response to an interaction.

Additionally, demographically supplied information, e.g. the user information 306, can be used as an event in updating the user profiles.

6. Measurements for Profile Events

Each of the events within the various categories of profile events 316 may be associated with a different confidence that is used to control adjustment of the user profile and item profile in response to the different types of interactions. This allows for differentiation between different types of events, for example a details event may be assigned a stronger confidence than a location event. The numerical confidence information is stored in box 320.

The confidences used by one embodiment of the invention, are that buy category events have a confidence of 1.0; details category events have a confidence of 0.50; customization category events have a confidence of 4.0; and navigation category events have a confidence of 1.0.

7. Relations between Parameters

As noted, the personality traits within the preference profiles may be interrelated. As discussed above, in connection with "Rapid Adaptation of the System," these relations describe how parameters are correlated. The relations are used to enforce known consistencies between the psychographic parameters of a user's, or item's, profile. For example, a baby is unlikely to have a high income, as such, there will be a negative correlation between "age (baby)" and "income (high vs. low)". This consistency between the psychographic parameters is used to more rapidly acquire a good estimate of the user's profile. It can be used to similar effect for items and their corresponding item profiles. As a result, in contrast to systems that do not use relations, a system using relations can provide better matches with fewer interactions.

The relations between parameters 322 can be constructed by assumptions about the parameters, or through statistical analysis of data sets, to determine correlations among the parameters. For example, analysis of the seeding values for all item profiles can be used to establish the relations between parameters 322. The remainder of this discussion will focus on a non-statistical approach to constructing the same.

The relations between parameters can be defined as a matrix R as seen in Equation 1.

$$Ru \approx [0] \quad (1)$$

Where u is a particular user profile, or an item profile. More specifically R can initially be composed as described in Equation 2.

$$R = \begin{bmatrix} r_{1,1}^T \\ r_{1,2}^T \\ \vdots \\ r_{q,q}^T \end{bmatrix} \quad (2)$$

Where q is the number of profile parameters. With each component vector, $r_{k,l}^T$, that is stacked in the matrix R describing one of the $\frac{q}{2}(q-1)$ possible relations between pairs of parameters. For example for twenty-six parameters, there would be 325 components of R .

Each $r_{k,l}^T$ component observes the property that $r_{k,l}^T u \approx 0$. Further, all the elements of the vector $r_{k,l}^T$ are 0 except for those at position k and l . The values in those two positions are as follows. If parameters k and l are likely to correspond closely, then positions k and l will be of opposite sign, and of a magnitude dependent on the strength of the correspondence. If the parameters are mutually exclusive, e.g. likely not to correspond, then positions k and l will be of the same sign and have a magnitude dependent on the extent of the exclusivity.

For example, consider R for an embodiment with only two parameters: age (baby), education (high vs. low), and income (high vs. low). There will be three rows in matrix R . Consider the row $r_{\text{age(baby), education (high vs. low)}}^T$. Let us assume that people with a strong personality trait of age (baby), parameter value "3", tend to be relatively uneducated, e.g. education parameter is low, "-3". Thus, we can provide the row as follows $[3 \quad 3 \quad 0]$. This row demonstrates the negative correlation between age (baby) and education (low). For less strongly

de-correlated parameters, the magnitude of the non-zero entries would be smaller.

The matrix R can be reduced in size by using singular value decomposition to produce a square matrix \tilde{R} relating each of the q parameters to the others.

To produce better estimates of user profiles and item profiles with fewer interactions, several rows of the matrix \tilde{R} can be removed by preserving only the $q - n$ most significant eigenvalues of \tilde{R} . More specifically, if \tilde{R} is given

by the formula $\tilde{R} = U \begin{bmatrix} S \\ 0 \end{bmatrix} V^T$, the reduced matrix, \bar{R} , is defined as $\bar{R} = \bar{S} \bar{V}^T$,

where \bar{S} is comprised of the $q - n$ upper rows of S and \bar{V} is comprised of the $q - n$ leftmost rows of V . \bar{R} is $q - n$ tall by n wide and observes Equation 1. A notable feature of the matrix \bar{R} is that it contains the relevant portions of R in a more compact form allowing for more rapid computation of user profiles and item profiles.

For the remainder of this discussion, it will be assumed that the matrix \bar{R} is used as the relations between the parameters 322 and it will simply be referred to as R .

8. Parameter Weights for Matching Engine

It may be helpful to assign different weights to different parameters within the preference profile for use during matching and filtering. For example, it may generally be the case that gender is a more important factor than a user's personality trait "flashy vs. conservative" in purchasing decisions. As such, a weighting vector may be used to assign relative weights to the parameters and stored as the parameter weights 324.

One such vector is shown in Equation 3 below with the weights listed in the order the parameters are presented in Table 1.

$$w = \{1.1806, 0.7232, 0.1010, 0.4340, 0.3290, 0.4479, 0.5138, 0.3316, 0.2708, 0.3927, 0.2669, 0.2156, 0.4498, 0.6488, 0.3454, 0.2153, 0.5754, 0.4663, 0.7146, 0.5799, 0.4880, 0.9935, 0.8485, 0.5405, 0.7850, 0.4565\} \quad (3)$$

It some instances, the weighting vector may be represented as a diagonal matrix W with zeroes for off-diagonal elements and the vector w in the diagonal elements.

Additionally, multiple vectors, w , for different categories within the taxonomy may be used. This may be useful if, within specific categories of the taxonomy, different weightings produce better matches. For example, when selecting among items within a category, e.g. women's clothing, it may be desirable to weight more heavily factors other than gender to allow better matches.

One approach to determining w is to look at a collection of interaction data for users and items. For example, among n users and m items, there may have already been a number of interactions. By selecting an initial weighting vector, w , e.g. equal to all ones, parameter values for users and items can be determined in response to that w . Then, by computing the match of each user with all items, a rank-ordered list of all m items can be produced for each of the n users. The matches of users to items used to generate the rank-ordered list for each user are generated using the matching formula, as described below. Then for each rank ordered list, the positions of the items that the user i has interacted with can be summed to produce a cost for that user with the weighting vector w .

For example, if the item j which the user i interacted with was in the 900th position in the rank ordered list and the only other item j' that the user i interacted with was in the 543rd position, the cost for the user i would be $900 + 543$, or 1443. Such sums can be added across all n users to produce a total cost for the weighting w .

Since the items that the user has interacted with already are items that are likely to interest the user, they should appear relatively earlier in the ranked

lists of all items. Therefore, by adjusting the vector w so that it minimizes the cost over all users, the weighting will be better as it will produce matches that place the items of greatest interest to users at the top of their respective lists.

Different initial values for w can be assumed. Then profiles can be re-determined and new rank ordered lists generated to produce total costs associated with the different values of w . A curve fit can be applied to the total cost values for each of the different w 's. A new w is selected that minimizes this curve. As desired, the value for w can be re-determined using this process as more interaction data becomes available.

9. Matching Formula

The matching formula 326 describes how to compare a user profile (u) and an item profile (p). Embodiments of the invention may use any, all, or some, of the formulas given in Equations 4A-D.

$$match = \sum_k (w_k (u_k - p_k))^2 \quad (4A)$$

$$match = \sum_k w_k^2 \left(\frac{u_k}{\|u_k\|_2} - \frac{p_k}{\|p_k\|_2} \right)^2 \quad (4B)$$

$$match = \sum_k w_k^2 \left(\left(\frac{u_k}{\|u_k\|_2} - \frac{p_k}{\|p_k\|_2} \right)^2 + \left(\frac{C_{k,k}^{user}}{\|u_k\|_2} + \frac{C_{k,k}^{item}}{\|p_k\|_2} \right) \right) \quad (4C)$$

$$match = \sum_k \frac{1}{\max(1, C_{k,k}^{user})} w_k \left| \frac{u_k}{\|u_k\|} - \frac{p_k}{\|p_k\|} \right| \quad (4D)$$

Where w is the weighting vector and k iterates across the parameters in the preference profile.

The different uses of the matching formulas in Equations 4A-D will now be explained; however, it is possible to use other formulas to compare user and item profiles.

Turning first to equation 4A, this is a simple weighted proximity comparison of the parameters of the user profile with those of the item profile. By minimizing the value of the match across different items, the best item for a

given user can be selected. Similarly, by minimizing the value of the match across different users, the best user for a given item can be selected.

Equation 4B normalizes the user profiles and item profiles to unit vectors to compensate for differing magnitudes of items, or user, profile vectors.

5 Equation 4C makes pessimistic adjustments to the profile vectors to factor in the confidences in the user, and item, profiles as expressed in the covariance matrices, C^{user} and C^{item} .

Equation 4D puts less weight on parameters that are less well know, e.g. low confidence/high covariance, while not excessively weighting well known
10 parameters, e.g. high confidence/low covariance.

Having described the configuration of the system, the operating environment, and the processes generally, the filtering and matching processes will now be described in greater detail.

F. Process Details

15 1. Filtering

The filtering process will now be described in greater detail. This process can be used by the filtering engine 114 according to the process 230. This will be done by first reviewing in detail some conceptual underpinnings of the approach. Then, a global solution will be discussed. Finally, an approach
20 supporting incremental updates, as used by some embodiments of the invention, will be discussed.

a. Concepts

One concept is that interactions -- falling into the categories of profile events -- are used to adjust user profiles and/or item profiles. Although the
25 interaction could comprise an explicit feedback to a particular item, e.g. rating the item, typically, the interactions will take the form of implicit feedback, e.g. click for more detail, click to buy, click to navigate, etc.

Another concept is that the global solution should be designed so as to have a single unique solution. Put differently, as feedback is incorporated, the user profiles and/or item profiles need to converge towards a single value that makes the best sense of the interaction data. Thus, some embodiments of the invention select a convex cost function to describe the global solution. As such, even as user profiles and/or item profiles are updated in response to interactions, the profiles will approach the global minimum of the cost function.

Another underlying concept is that the robustness of the system can be used by applying filtering approaches to improve the results. More specifically, filtering approaches allow for the best estimation of user profiles and item profiles given the uncertainty associated with measuring these parameters through interactions. Filtering better enables the incremental update approach that best matches the global solution to the problem.

b. Global Solution

A number of different cost functions can be used, the most preferable cost functions are convex with a global minimum. One such preferred cost function is described below.

The global cost function *Cost* describes the formulation of the problem. The component summands of the *Cost* function will be described in turn and then an equation for the cost function will be provided.

Minimizing the summand in equation 5 determines the user and item profiles to take into account interactions that have occurred.

$$\sum_{(i,j) \in Q} (u_i - p_j)^T W^T W (u_i - p_j) \frac{1}{\text{conf}_{i,j}} \quad (5)$$

Where *W* is the diagonal matrix including the parameter weights. The set $Q = \{(i, j) : \text{user } i \text{ has clicked on item } j\}$. Thus, if user #10, e.g. John Doe, has clicked on a given item #30, e.g. the Hawaiian vacation, the set *Q* would contain the element (10, 30). Where, *conf_{i,j}* is a measurement for that type of interaction. For example, given the confidences in different categories of events

described in the Configurations and Initialization section above, if the interaction was a detail event, the confidence would be 0.50. In some embodiments of the invention, multiple interactions between the same user and the same item are accounted for.

- 5 Minimizing the summands in equations 6 and 7 decreases the extent to which user profile and item profile parameters violate the relations between parameters 322 as encoded in matrix R .

$$\sum_i u_i^T R^T C^{R^{-1}} R u_i \quad (6)$$

$$\sum_j p_j^T R^T C^{R^{-1}} R p_j \quad (7)$$

- Where i and j iterate over the set of all users and items respectively. Where
 10 C^R is the covariance matrix describing the degree of confidence in the assumed relations amongst the parameters. A small value for C^R indicates that equation (1) should be very close to zero. Also, any of the three various forms for the matrix R can be used.

- Minimizing equations 8 and 9 decreases the extent to which user profile
 15 and item profile parameters deviate from the assumed, e.g. seeded, values for the respective users/items.

$$\sum_j (p_j - \alpha_j)^T C^{\alpha^{-1}} (p_j - \alpha_j) \quad (8)$$

$$\sum_i (u_i - \beta_i)^T C^{\beta^{-1}} (u_i - \beta_i) \quad (9)$$

- Where i and j iterate over the set of all users and items respectively. α_j refers to the seeded profile for the item j , for example as determined by its placement in
 20 the taxonomy 308 and the profile for that category of the taxonomy. Similarly, β_i refers to the seeded profile for the user i as determined by the user information 306, if available. The matrices C^{α} and C^{β} correspond to covariance matrices expressing the confidence in the seeded values, e.g. the covariance matrix for the seeded profile.

- 25 The global cost function is described by Equation 10.

$$Cost = Eqn.5 + Eqn.6 + Eqn.7 + Eqn.8 + Eqn.9 \quad (10)$$

Minimizing this function determines the optimal estimates for the user and item profile parameters for the given set of interactions.

5 Still other cost functions may be used when negative interactions are being tracked as well, e.g. "User did not click on item *i*", "User indicated they dislike item *i*", etc. Such cost functions should be designed so as to be convex and produce a unique global solution.

Generally, global cost functions are not practical to implement since they are computational intensive for current computers. Additionally, it is often
10 valuable to provide incremental updates to item and user profiles as, or shortly after, each interaction occurs, rather than batch updates as would be typically provided when minimizing a global cost function. Accordingly, the approach described below, using the Kalman filter, may be used for incremental updates.

c. Incremental Updates with Filtering

15 Figure 4 illustrates one embodiment of a process for incrementally updating user and item profiles using the filtering engine 114, this could be used as the process 230. The respective user profile 400 and item profile 402 for the user and item involved in a given interaction can be retrieved from the profile database 118.

20 The case of interactions falling into the customization and navigation event profile categories is handled similarly to those for detail and buy event profile categories. For customization and navigation events, the preference profile for that customization and/or navigation event may be updated in the same fashion as an item profile.

25 Figure 4 will be explained with respect to updating a user profile. The process for updating an item profile is identical in nature as seen in the bottom half of Figure 4.

The first step in the process, step 406 (and 408 for items), is to describe the interaction in terms of a measurement. The measurement is based upon both

the user profile, u_{in} , and the item profile, p_{in} , prior to the interaction and the interaction. In the specific case where the Kalman filter is used, as described below, the development of the measurement corresponds to equations 11-14.

The next step in the process, step 410 (and 412 for items), is the
5 estimation of the new user profile, e.g. u_{out} . This new estimation can be generated through use of the measurement from the previous step. In the specific case where the Kalman filter is used, as described below, the estimation of the new user profile corresponds to equations 15-18.

Thus, other measurement and estimation approaches may be used aside
10 from the Kalman filter approach described below.

i. Kalman Filter Principles

The filtering process used at step 412 can be the Kalman filter, or other suitable filters. More generally, any optimal recursive data processing algorithm may be used. Though the term optimal may have a number of meanings
15 depending on the criteria chosen to evaluate performance, the Kalman filter has been shown to be optimal under a reasonable set of criteria for linear systems problems. See, Peter S. Maybeck, Stochastic Models, Estimation, and Control, (Academic Press 1979) Vol. 1, at 4, (available at
<<http://www.cs.unc.edu/~welch/kalman/maybeck.html>> (hereinafter
20 Maybeck).

Thus, the Kalman filter can process all available measurements, regardless of their precision, and produce an estimate of the current value of the variables of interest. *Maybeck*, at 4. Thus, turning to the use of the Kalman filter in embodiments of the invention, interactions, even if the corresponding
25 measurement is not particularly precise, can be used to estimate the user profile and/or item profile.

The estimate is produced using prior (1) knowledge about the system and the errors inherent in the measurements; (2) a statistical description of the system noises, measurement errors, and uncertainty of the model; and (3) all
30 available information about initial conditions for the variables of interest.

Maybeck, at 4. Thus, turning again to the use of the Kalman filter by embodiments of the invention, the components necessary for (1)-(3) above stem from information established in the initialization and configuration, see "Initialization and Configuration" above, and/or from updates to that
5 information arising from interactions.

Most generally, the term "optimal estimate" as used in filtering refers to a filter minimizing errors in some respect. *Maybeck*, at 5. Thus, from a Bayesian viewpoint, the filter should propagate the conditional probability density function. *Maybeck*, at 5. The Kalman filter performs this propagation for
10 problems in which the system can be described with a linear model, provided that certain additional assumptions are made about the system and measurement noises. *Maybeck*, at 7. The optimal estimate for the Kalman filter may be any of the mean, "center of probability" estimate; the mode, value of the variables with highest probability or the peak of the density; or the median, the value of the
15 variables such that equal amounts of the probability weights lie on either side. Because of the general nature of the assumptions about the noise, and the fact that the assumptions make the filtering problem computationally tractable, the Kalman filter is suitable for application to the instant problem and is used by embodiments of the invention to update and estimate the user profile and/or
20 item profile in response to feedback, measurements.

Further information about the Kalman filter is described in G.F. Franklin, J.D. Powell, and M.L. Workman, Digital Control of Dynamic Systems, (2nd Ed., Addison-Wesley 1990) and D.P. Bertsekas, Nonlinear Programming, (2nd Ed., Athena Scientific 1995), Volume 1. The remainder of
25 the discussion will assume that the Kalman filter is used.

ii. Kalman Filter Application

In order to apply the Kalman filter, a measurement of the parameters is assumed from each interaction. This assumed measurement results in the measurement vector, z . The Equations 11-14 set forth the determination and
30 form of z and will be described more fully below.

45

$$z = Hu_{in} + N \quad (11)$$

$$H = \begin{bmatrix} [W] \\ [R] \\ [I] \end{bmatrix} \quad (12)$$

$$R_u \approx \begin{bmatrix} W^T C_{in}^{item} W + conf_{i,j} & 0 \\ 0 & C^R \\ & C^\beta \end{bmatrix} \quad (13)$$

$$z = \begin{bmatrix} Wp_{in} \\ [0] \\ \beta_i \end{bmatrix} \quad (14)$$

The matrix H relates measurement vector z with the user profile parameters being measured. H is defined in terms of earlier configuration and initialization values. The composition of H can be derived from the global cost function that the filtering approach is attempting to minimize in an iterative form.

The matrix N is the assumed measurement noise that conceptually describes the imprecision of the assumed measurement. N is a mathematical construct not computed by embodiments of the invention. R_u , the expected covariance of N , can be estimated according to the approximation provided in equation 13. In mathematical terms, $R_u = E(N^T N)$, where $E(x)$ is the expectation value for the random variable x . Note, that the computation of R_u includes the $conf_{i,j}$ that differentiates between the relative weights of different categories of interactions. Additionally, R_u includes the effects of the uncertainty in the item parameters used to update the user parameters.

The measurement vector z is comprised as shown in equation 14. The three components of z correspond to the weighted item parameters used to update the user parameters, the interrelation between the parameters, assumed to result in a zero measurement per equation 1, and the seeded profile parameters for the item.

One optimization that can be used is to further sub-divide the update process. This allows the user profile and item profile to be run through the Kalman filter with some blocks within equations 11-14 omitted. Thus, for

example, within equation 12 for H , the blocks for the relation matrix and the identity matrix could be omitted. The corresponding blocks would then be omitted in equations 13-14 and the Kalman filter applied. Later, an update using the previously omitted blocks can be performed.

- 5 Now, the equations of the Kalman filter as used by embodiments of the invention will be set forth in Equations 15-18, then a description of the filtering process and the equations follows.

$$K = C_{in}^{user} - H^T (H^T C_{in}^{user} H + R_u)^{-1} \quad (15)$$

$$C_{int}^{user} = (I - KH) C_{in}^{user} \quad (16)$$

$$u_{out} = u_{in} + K(z - H u_{in}) \quad (17)$$

$$C_{out}^{user-1} = (C_{int}^{user} + Q)^{-1} \quad (18)$$

- 10 Equation 15 computes the interim value, K . The interim value is a matrix of linear feedback terms that are used to update the user profile parameters based on the measurement and confidences. The matrix C_{in}^{user} is the covariance matrix corresponding to the confidences in the user profile u_{in} . More specifically, for the assumptions described, $C_{in}^{user} = E(u_{in} - E(u_{in}))(u_{in} - E(u_{in}))$, where $E(x)$ is the expectation value for the random variable x .

- 15 Once the interim value K is computed, an intermediate update to the confidences in the user parameters can be computed according to equation 16. The interim value is stored in the covariance matrix C_{int}^{user} .

- 20 Also, updated user profile parameters are computed according to equation 17 and stored in u_{out} . u_{out} is an improved estimate of the user's psychographic profile.

- Lastly, the memory of the Kalman filter can be preserved according to equation 18. Q represents uncertainty in the model used and prevents the filter from assuming too high a degree of certainty in the user parameters, by increasing the covariances.

- 25 Although incremental updates with a filter such as the Kalman filter enables rapid updates after receiving feedback, it may be desirable to better

estimate the user profile and item profile by re-applying the filter to a sequence of interactions.

Specifically, consider if the user first interacts with item #1, then item #2, then item #3. The process as shown in Figure 4, suggests that those updates would occur sequentially with, each interaction considered only once. In fact, the filter can be re-applied between the user and item #1 after the application of the filter to item #2 and/or item #3. This is sensible because after applying the filter to update the user profile and the profile for item #2, information about the user is known with a higher degree of confidence, resulting in smaller covariances.

Accordingly, in some embodiments of the invention, the interaction data can be "smoothed" in an offline process that applies the filter to the sequence of interactions of users with items forwards and backwards. For example, if the first interaction was with item #78, and the last interaction was with item #10, the filter could be re-applied to the interactions first in the order they occurred, first interaction (#10) to last interaction (#78). Then, the filter can be re-applied to the interaction in reverse order, e.g. last interaction (#78) to first interaction (#10).

2. Matching

As described above in conjunction with the matching formula 326, the matching engine 116 can use a matching formula and select the items with the lowest result for a given user. In other instances, the best n items may be shown to the user. In other instances, a list of items may be presented in sorted order from best match to worst match.

Some alternative embodiments of the invention will now be described.

G. Alternative Embodiments

1. Users and Items Interchangeable in the Methods

Although the invention has primarily been described in terms of
embodiments for matching users with items, embodiments of the invention can
5 do the reverse, match items with users. Thus, a new item can be targeted to
users that are likely to be interested for marketing, research, and/or other
purposes easily. For example, the best n matching users for a new product could
be sent an advertisement.

2. Guiding Users to Interesting Items of their Choice with Explicit 10 Interactions

The embodiments of the invention described to this point have
primarily, or exclusively, relied on implicit interactions, e.g. the user clicked on
something, as opposed to explicit ratings interactions, e.g. "I rate this 3 out of
3".

15 Some embodiments of the invention may be used with systems that
support types of explicit ratings interactions. These systems may be used to
allow a user to more directly drive the selection of items of interest. One
example of such a use in a server environment allows the user to guide the
selection and identification of documents of interest.

20 A more detailed description of these embodiments of the invention will
be provided with reference to Figures 5-9

Figure 5 illustrates an exemplary web page supporting the explicit rating
features. The web page 500, as seen on the web browser 100, is shown. The
web page 500 includes two elements, the element 502 and the element 504.
25 Additionally, the cursor 506 is shown. The elements 502 and 504 may be any
portion of the web page 500, but most typically, the elements 502 and 504 are
links on the web page 500.

It may be the case that the elements on the web page 500 have been rank ordered according to the match between the corresponding item profiles for the elements and the user profile. Three separate functionalities are supported through the use of the feedback or rating bar: (1) the collection of explicit rating
5 interactions on the currently displayed web page (e.g. the web page 500); (2) providing efficient links to new items (e.g. other web pages); and (3) the display to the user of the strength of the match between the user and the linked items.

Accordingly, as shown in Figure 6, a predicted rating 600 may be displayed when the cursor 506 is positioned over an element 502. The predicted
10 rating 600 may be a graphical, textual, auditory, and/or other output of the strength of the match between the user profile and the item profile of the linked item. In this example, the predicted rating 600 is displayed with a pop-up visual indicator. In other embodiments, the visual indicator may be present next to, or within the display of, the element 502. For example, adjacent to the element
15 502, the confidence in the strength of the match for the user with that item could be displayed at all times.

Typically, the confidence in the predicted rating between a user is expressed relative to best and worst matching items for the user, e.g. the items with minimum and maximum match values according to the match formula 326.
20 As such, the type of control shown in Figure 9 would typically be used to show the predicted rating 600. When a control (e.g. the control in Figure 9) is used to show the predicted rating 600, its value typically cannot be adjusted.

The ability to collect explicit rating interactions about the currently displayed web page is supported through the use of a feedback bar 700 as
25 shown in Figure 7. When the user selects an element, e.g. the element 504, a pop-up visual input control may be provided to allow the user to express her/his preferences towards the page she/he is currently on. Thus as the user is departing the web page 500 by way of a click on the element 504, she/he gets to explicitly rate her/his opinions about that page. The rating is accomplished by
30 movement of the cursor to the left or right, while the mouse button remains held down, causes an update to an indicator within the control showing the current

setting. Releasing the mouse button causes the indicated setting to be adopted as the user's explicit rating interaction. Additionally, the delivery of the appropriate linked web page can then commence.

Figures 8 and 9 show possible feedback and rating controls for use with these embodiments of the invention. If negative feedback is permitted, the control of Figure 8 may be used to indicate a negative reaction (to the left of center) or a positive reaction (to the right of center), the distance from the center indicates the magnitude of the reaction (further is stronger). When only positive feedback is being used, a control such as the one in Figure 9 can be used and the magnitude of the feedback is determined by the distance from the left edge (minimum level of positive feedback).

Other embodiments of the invention may allow the control indicator to be adjusted and set with the mouse button up, immediately after a click on the element 504. In these embodiments, a second mouse click would set the rating and trigger the delivery of the appropriate linked web page. The specific global cost function and filtering equation described in "Process Details", above, do not handle negative feedback; although, the approaches described therein can be used to handle negative feedback to update the user and item profiles as described.

20 3. Privacy Aspects

Embodiments of the invention are capable of supporting a number of privacy platform requirements. For example, the profile of psychographic traits for the user can be presented in human understandable terms. Further, to the extent required by such privacy platforms, e.g. P3P, the system can allow a user to adjust her/his own profile, e.g. explicitly set/change one or more parameter values. Once set, the modified parameter values may continue to be adjusted normally.

4. Item Adjustments

A feature offered by some embodiments of the invention is that a site operator can adjust the profile associated with one or more items. This may be useful in a number of embodiments. For example, a vendor, or manufacturer, may wish to re-target an item. For example, the producer of an item that has been considered a luxury good might wish to re-target the item to a more cost-conscious audience in conjunction with new pricing, advertising, branding, etc. As such, the item profile can be adjusted in the same fashion that user profiles can be adjusted as described above.

5. Additional Embodiments

In some embodiments, filtering engine 114 and the matching engine 116 can be hardware based, software based, or a combination of the two. In some embodiments, filtering programs and matching programs are included in one or more computer usable media such as CD-ROMs, floppy disks, or other media. In some embodiments, equations for use in filtering programs and matching programs are included in one or more computer usable media.

Some embodiments of the invention are included in an electromagnetic wave form. The electromagnetic waveform comprises information such as filtering programs, matching programs, and equations for use in filtering programs. The electromagnetic waveform may include the filtering programs and/or matching programs accessed over a network. The electromagnetic waveform can comprise information such as preference profiles; relations amongst parameters, e.g. R ; seeded profiles for categories within a taxonomy, matching formulas; weightings for the parameters, e.g. w , a global cost function, e.g. $Cost$; and/or other settings, initialized values, and/or formulae used by embodiments of the invention accessed over a network.

H. Conclusion

The foregoing description of various embodiments of the invention has been presented for purposes of illustration and description. It is not intended to limit the invention to the precise forms disclosed. Many modifications and
5 equivalent arrangements will be apparent.

CLAIMS

What is claimed is:

1. A method of matching a user with an item of interest using a computer system, the computer system including a user specific psychographic parameter values indicating psychographic traits for the user, the computer system further including a set of item specific psychographic parameter values, each of the set of item specific psychographic parameter values corresponding to an item and indicating psychographic traits of users interested in the corresponding item, the method comprising:
 - responsive to receiving interaction data, the interaction data corresponding to events from which psychographic information can be obtained for the user, updating the user specific psychographic parameter values and the set of item specific psychographic parameter values; and
 - responsive to receiving the request to find an item, performing the following,
 - accessing the user specific psychographic parameter values,
 - accessing the set of item specific psychographic parameter values,
 - and
 - selecting the item of interest to the user, the item being selected based upon the proximity of the corresponding item specific psychographic parameter values to the user specific psychographic parameter values.
2. The method of claim 1 wherein the user specific psychographic parameter values and each of the item specific psychographic parameter values are associated with a corresponding set of confidence values, and wherein the selecting the item uses the confidence values to select a best match.

3. The method of claim 1 further comprising initializing the computer system including accessing a predefined set of psychographic parameters, wherein the set of psychographic parameters corresponds to at least the following personality types: sex (male or female), materialistic or non-materialistic, cost conscious or extravagant, socially liberal or socially conservative, libidinous or asexual, and technical or non-technical.
- 5
4. The method of claim 1 further comprising initializing the computer system including accessing a set of correlation values, the set of correlation values correlating between psychographic parameters, the set of correlation values being used in updating the user specific psychographic parameter values and the set of item specific psychographic parameter values.
- 10
5. The method of claim 1 further comprising initializing the computer system including accessing a set of parameter weight values, the set of parameter weight values used to determine the relative relevance of the user specific psychographic parameter values for any item.
- 15
6. The method of claim 1 wherein receiving interaction data includes receiving data about an event corresponding to a user's click on a banner advertisement.
7. The method of claim 1 wherein receiving interaction data includes receiving data about an event corresponding to a user's request for more information on an item.
- 20
8. The method of claim 1 wherein receiving interaction data includes receiving data about an event corresponding to a user's request to purchase an item.
- 25
9. The method of claim 1 wherein receiving interaction data includes receiving data about at least the following events: a user's request for more information, a user's request to purchase an item, a user's request to customize a system, and a user's request to navigate in a system.

10. The method of claim 1 wherein updating the user specific psychographic parameter values includes applying a Kalman filter to optimally update the user specific psychographic parameter values.
11. The method of claim 1 wherein the selecting comprises selecting the
5 item producing the minimum value for a predetermined matching function computed on the user profile and the item profile as the item of interest to the user.
12. The method of claim 1 further comprising receiving explicit data about the psychographic traits of the user and incorporating the explicit data into the
10 user specific psychographic parameter values.
13. A computer system to match a user with an item of interest, the computer system comprising:
- a memory storing a user specific psychographic parameter values indicating psychographic traits for the user, the memory further
15 storing a set of item specific psychographic parameter values, each of the set of item specific psychographic parameter values corresponding to an item and indicating psychographic traits of users interested in the corresponding item, the memory storing first program code and second program code;
- 20 a processor, coupled to the memory, the processor for executing the first program code responsive to receiving interaction data, the interaction data corresponding to events from which psychographic information can be obtained for the user, the first program further for updating the user specific psychographic parameter values and the
25 set of item specific psychographic parameter values, the processor further for executing the second program code responsive to receiving the request to find an item, the second program code for accessing the user specific psychographic parameter values, and accessing the set of item specific psychographic parameter values,
30 the second program code further for selecting the item of interest to

the user, the item being selected based upon the proximity of the corresponding item specific psychographic parameter values to the user specific psychographic parameter values.

14. A computer system for matching a user with an item of interest using a
5 computer system, the computer system including a user specific psychographic parameter values indicating psychographic traits for the user, the computer system further including a set of item specific psychographic parameter values, each of the set of item specific psychographic parameter values corresponding to an item and indicating psychographic traits of users interested in the
10 corresponding item, the computer system comprising:
means, responsive to receiving interaction data, the interaction data corresponding to events from which psychographic information can be obtained for the user, for updating the user specific psychographic parameter values and the set of item specific psychographic
15 parameter values; and
means, responsive to receiving the request to find an item, for performing the following,
accessing the user specific psychographic parameter values,
accessing the set of item specific psychographic parameter values,
20 and
selecting the item of interest to the user, the item being selected based upon the proximity of the corresponding item specific psychographic parameter values to the user specific psychographic parameter values.
- 25 15. A method of matching an item with a user likely to be interested in the item using a computer system, the computer system including an item specific psychographic parameter values indicating traits of users interested in the item, the computer system further including a set of user specific parameter values, each of the set of user specific parameter values corresponding to a user and

indicating psychographic traits of the corresponding user, the method comprising:

- responsive to receiving interaction data, the interaction data corresponding to events from which psychographic information can be obtained for the item, updating the item specific psychographic parameter values and the set of user specific psychographic parameter values; and
- responsive to receiving the request to identify a user, performing the following steps,
- accessing the item specific psychographic parameter values, accessing the set of user specific psychographic parameter values, and
- identifying the user interested in the item, the user being identified based upon the proximity of the corresponding user specific psychographic parameter values to the item specific psychographic parameter values.

16. The method of claim 15 wherein the item specific psychographic parameter values and each of the user specific psychographic parameter values are associated with a corresponding set of confidence values, and wherein the identifying the user uses the confidence values to select a best match.

17. The method of claim 15 further comprising initializing the computer system including accessing a predefined set of psychographic parameters, wherein the set of psychographic parameters corresponds to at least the following personality types: sex (male or female), materialistic or non-materialistic, cost conscious or extravagant, socially liberal or socially conservative, libidinous or asexual, and technical or non-technical.

18. The method of claim 15 further comprising initializing the computer system including accessing a set of correlation values, the set of correlation values correlating between psychographic parameters, the set of correlation

values being used in updating the user specific psychographic parameter values and the set of item specific psychographic parameter values.

19. The method of claim 15 further comprising initializing the computer system including accessing a set of parameter weight values, the set of
5 parameter weight values used to determine the relative relevance of the user specific psychographic parameter values for any item.

20. The method of claim 15 wherein receiving interaction data includes receiving data about an event corresponding to a user's click on a banner advertisement.

10 21. The method of claim 15 wherein receiving interaction data includes receiving data about an event corresponding to a user's request for more information on an item.

22. The method of claim 15 wherein receiving interaction data includes receiving data about an event corresponding to a user's request to purchase an
15 item.

23. The method of claim 15 wherein receiving interaction data includes receiving data about at least the following events: a user's request for more information, a user's request to purchase an item, a user's request to customize a system, and a user's request to navigate in a system.

20 24. The method of claim 1 wherein updating the item specific psychographic parameter values includes applying a Kalman filter to optimally update the item specific psychographic parameter values.

25. The method of claim 1 wherein the selecting comprises selecting the user producing the minimum value for a predetermined matching function
25 computed on the item profile and the user profile as the user of interest for the item.

26. The method of claim 1 further comprising receiving explicit data about the psychographic traits of users and incorporating the explicit data into the corresponding user specific psychographic parameter values.

27. A computer system to identify a user likely to be interested in an item,
5 the computer system comprising:

a memory storing an item specific psychographic parameter values
indicating psychographic traits of users interested in the item, the
memory further storing a set of user specific psychographic
parameter values, each of the set of user specific psychographic
10 parameter values corresponding to an user and indicating
psychographic traits of the corresponding user, the memory storing
first program code and second program code;
a processor, coupled to the memory, the processor for executing the first
program code responsive to receiving interaction data, the
15 interaction data corresponding to events from which psychographic
information can be obtained for the item, the first program further
for updating the item specific psychographic parameter values and
the set of user specific psychographic parameter values, the
processor further for executing the second program code responsive
20 to receiving the request to find a user, the second program code for
accessing the item specific psychographic parameter values, and
accessing the set of user specific psychographic parameter values,
the second program code further for selecting the item of interest to
the user, the user being selected based upon the proximity of the
25 corresponding user specific psychographic parameter values to the
item specific psychographic parameter values.

28. A method for matching an item with a user likely to be interested in the
item and updating information about the user and the item using a computer
system, the computer system including a web server, the computer system
30 including a user specific psychographic parameter values indicating

60

psychographic traits for the user, the computer system further including a set of item specific psychographic parameter values, each of the set of item specific psychographic parameter values corresponding to an item and indicating psychographic traits of users interested in the corresponding item, the method comprising:

- 5 receiving a request at the web server, the request being formatted as an Internet protocol request for a data;
- determining the source of the request to identify a corresponding user specific psychographic profile and accessing the corresponding user specific psychographic parameter values;
- 10 the web server transmitting a response to the request, the response including item information, the item information being selected by accessing the user specific psychographic parameter values, accessing the set of item specific psychographic parameter values,
- 15 selecting the item of interest to the user, the item being selected based upon the proximity of the corresponding item specific psychographic parameter values to the user specific psychographic parameter values, and
- accessing the item information corresponding to the item of interest;
- 20 the web server receiving an interaction event, the interaction event defining an interaction between the user and the item information;
- and
- using the interaction event to update the user specific psychographic parameter values and the set of item specific psychographic parameter values.
- 25

29. The method of claim 28 wherein the request includes a Hypertext Transfer Protocol (HTTP) request.

30. The method of claim 28 wherein the computer system includes a user identifier information, the user identifier information identifying the user, and

30 wherein the computer system further includes a database of user profiles,

wherein the corresponding user specific psychographic profile is included in the database and wherein determining the source of the request to identify the corresponding user specific psychographic profile includes searching the database using the user identifier information.

- 5 31. The method of claim 28 wherein determining the source of the requests includes transmitting a request for cookie information, the cookie information identifying the user.
32. The method of claim 28 wherein the item is associated with a banner advertisement and wherein transmitting the response includes transmitting the
10 banner advertisement.
33. The method of claim 28 wherein the item is associated with a banner advertisement and wherein transmitting the response includes transmitting the banner advertisement, and wherein the web server receiving the interaction event corresponds to receiving a signal indicating that a user clicked on the
15 banner advertisement.
34. The method of claim 28 wherein the item is associated with a sales information and wherein transmitting the response includes transmitting the sales information, and wherein the web server receiving the interaction event corresponds to receiving a signal indicating that a user purchased the item.
- 20 35. A method of initializing an user profile using a computer system, the computer system including a user specific psychographic parameter data structure indicating psychographic traits for the user, the psychographic parameter data structure defining a set of psychographic parameters, the method comprising:
- 25 receiving user specified data;
determining a correlation between the user specified data and the psychographic parameters;

updating the values in the data structure using the information about the correlation between the user specified data and the psychographic parameters.

36. The method of claim 35 wherein the user specified data includes
5 demographic information about the user and wherein the correlation between the user specified data and the psychographic parameters is determined by statistically correlating demographics with psychographics.

37. The method of claim 35 wherein the user specified data includes
information about the user's gender, wherein the psychographic parameters
10 includes a male vs. female trait, and wherein the updating the values in the data structure includes updating the values in the data structure corresponding to the male vs. female trait, using the gender information.

38. A method of initializing an item profile using a computer system, the
computer system including a item specific psychographic parameter data
15 structure indicating psychographic traits of users interested in the item, the psychographic parameter data structure defining a set of psychographic parameters, the method comprising:

receiving categorization data, the categorization data indicates a
category in which the item is classified;
20 accessing a set of psychographic parameters values for items in the category;
updating the values in the data structure using the set of values.

39. The method of claim 38 wherein the categorization data is associated
with a taxonomy of categories, and wherein each category has an associated set
25 of psychographic parameters, and wherein the item is associated with the category.

40. The method of claim 38 wherein the categorization data is associated
with a taxonomy of categories, wherein each category has an associated set of

psychographic parameters, and wherein the item is associated with the category, and wherein the taxonomy corresponds to a least a portion of the United Nations Standard Products and Service Codes (UN/SPSC) taxonomy.

- 5 41. A method of generating transportable psychographic profiles using a computer system, a transportable psychographic profile being a psychographic profile that can be used independently of the input events used to generate the profile, the method comprising:
- 10 accessing a set of psychographic parameters, each parameter
 corresponding to a personality trait;
 responsive to receiving interaction data, the interaction data
 corresponding to events from which psychographic information can
 be obtained;
 creating psychographic profiles of the items and users corresponding to
15 the interaction data; and
 updating the transportable psychographic profiles from the interaction
 data.
42. A method of converting a first set of psychographic profiles to a second
set of psychographic profiles using a computer system, each set of
20 psychographic profiles being defined according to a corresponding, but
different, set of psychographic parameters, the method comprising:
- accessing a first set of psychographic parameters, each parameter
 corresponding to a personality trait;
 accessing a set of translation values, the set of translation values
25 defining a relationship between each psychographic parameter in the
 first set and at least some psychographic parameters in the second
 set; and
 converting the first set to the second set using the translation values.
43. The method of claim 42 wherein the first set corresponds to a smaller set
30 of psychographic parameters than the second set.

44. The method of claim 42 wherein the confidence values corresponding to the first set are also converted to the second set.

45. A method of conducting a commercial transaction using a computer system, the computer system including a user specific psychographic parameter values indicating psychographic traits for the user, the computer system further including a set of item specific psychographic parameter values, each of the set of item specific psychographic parameter values corresponding to an item and indicating psychographic traits of users interested in the corresponding item, the method comprising:

10 receiving a request at the computer system for information about the item;

determining the source of the request to identify a corresponding user specific psychographic profile and accessing the corresponding user specific psychographic parameter values;

15 the computer system transmitting a response to the request, the response including item information, the item information being selected by accessing the user specific psychographic parameter values, accessing the set of item specific psychographic parameter values, selecting the item of interest to the user, the item being selected

20 based upon the proximity of the corresponding item specific psychographic parameter values to the user specific psychographic parameter values, and

accessing the item information corresponding to the item of interest;

the computer system receiving an interaction event, the interaction event

25 indicating a purchase of the item by the user; and

using the interaction event to update the user specific psychographic parameter values and the set of item specific psychographic parameter values.

46. A method of supporting a commercial transaction using a computer system, the computer system including a user specific psychographic parameter

30

65

values indicating psychographic traits for the user, the computer system further including a set of item specific psychographic parameter values, each of the set of item specific psychographic parameter values corresponding to an item and indicating psychographic traits of users interested in the corresponding item, the

5 method comprising:

receiving a request at the computer system for information about the item;

determining the source of the request to identify a corresponding user specific psychographic profile and accessing the corresponding user specific psychographic parameter values; and

10

the computer system transmitting a response to the request, the response including item information, the item information being selected by accessing the user specific psychographic parameter values,

accessing the set of item specific psychographic parameter values, selecting the item of interest to the user, the item being selected based upon the proximity of the corresponding item specific psychographic parameter values to the user specific psychographic parameter values, and

15

accessing the item information corresponding to the item of interest, wherein the item information corresponds information about how to purchase the item.

20

47. A method of allowing a user to view and update a corresponding user profile using a computer system, the computer system including a user specific psychographic parameter data structure indicating psychographic traits for the user, the psychographic parameter data structure defining a set of psychographic parameters, the method comprising:

25

receiving a request to view the data in the user data structure, the request identifying the source of the request;

accessing the corresponding data structure;

transmitting the data in the data structure;

30

receiving a request to update the data in the data structure; and

48. A method of allowing a user to view and update a corresponding user profile using a computer system, the computer system including a web server and a database, the database including a user specific psychographic parameter data structure indicating psychographic traits for the user, the psychographic parameter data structure defining a set of psychographic parameters, the method comprising:
- 5 receiving an Internet protocol formatted request to view the data in the user data structure, the request identifying the source of the request; accessing the corresponding data structure from the database;
- 10 transmitting the data in the data structure as an Internet protocol formatted response;
- receiving an Internet protocol formatted request to update the data in the data structure; and
- modifying the data in the data structure responsive to the request.
- 15 49. The method of claim 48 wherein the response includes human readable names associated with the psychographic traits defined in the data structure.
50. The method of claim 48 wherein the response includes HTML code.
51. The method of claim 48 wherein at least some of the data in the response is formatted in XML code.
- 20 52. A method of matching an item with a group of users likely to be interested in the item using a computer system, the computer system including an item specific psychographic parameter values indicating traits of users interested in the item, the computer system further including a set of user specific parameter values, each of the set of user specific parameter values
- 25 corresponding to a user and indicating psychographic traits of the corresponding user, the method comprising:
- responsive to receiving interaction data, the interaction data corresponding to events from which psychographic information can be obtained for the item, updating the item specific psychographic

parameter values and the set of user specific psychographic
parameter values; and
responsive to receiving the request to identify a user, performing the
following steps,
5 accessing the item specific psychographic parameter values,
 accessing the set of user specific psychographic parameter values,
 and
 identifying the group of users interested in the item, the group of
 users being identified based upon the proximity of the
10 corresponding user specific psychographic parameter values to
 the item specific psychographic parameter values.

53. A method of contacting a group of users likely to be interested in an
item using a computer system, the computer system including an item specific
psychographic parameter values indicating traits of users interested in the item,
15 the computer system further including a set of user specific parameter values,
 each of the set of user specific parameter values corresponding to a user and
 indicating psychographic traits of the corresponding user, the method
comprising:

 responsive to receiving interaction data, the interaction data
20 corresponding to events from which psychographic information can
 be obtained for the item, updating the item specific psychographic
 parameter values and the set of user specific psychographic
 parameter values;
 responsive to receiving the request to identify a user, performing the
25 following steps,
 accessing the item specific psychographic parameter values,
 accessing the set of user specific psychographic parameter values,
 and
 identifying the group of users interested in the item, the group of
30 users being identified based upon the proximity of the

corresponding user specific psychographic parameter values to the item specific psychographic parameter values; and transmitting information about the item to the group of users.

54. A method of emailing a group of users likely to be interested in an item
- 5 using a computer system, the computer system including an item specific psychographic parameter values indicating traits of users interested in the item, the computer system further including a set of user specific parameter values, each of the set of user specific psychographic parameter values corresponding to a user and indicating psychographic traits of the corresponding user, the
- 10 computer system being coupled to the Internet, the method comprising:
- responsive to receiving interaction data, the interaction data corresponding to events from which psychographic information can be obtained for the item, updating the item specific psychographic parameter values and the set of user specific psychographic
- 15 parameter values;
- responsive to receiving the request to identify a user, performing the following steps,
- accessing the item specific psychographic parameter values,
- accessing the set of user specific psychographic parameter values,
- 20 and
- identifying the group of users interested in the item, the group of users being identified based upon the proximity of the corresponding user specific psychographic parameter values to the item specific psychographic parameter values;
- 25 determining the set of email addresses associated with the group of users; and
- transmitting a set of email messages to the group of users using the set of email addresses, the set of email messages including information about the item.

55. The method of claim 54 wherein at least some of the email messages are customized according to the personality traits indicated in the associated user specific psychographic parameter values.

56. A method of serving a banner advertisement from an internet site, the internet site being run on a computer system, the computer system being coupled to the internet, the method comprising:

receiving a banner advertisement request, the banner advertisement request being associated with a user;

accessing a user profile corresponding to the user, the user profile including first values, the first values being values of psychographic parameters, the psychographic parameters indicating personality traits, the first values indicating the personality traits of the user; accessing a set of banner advertisement profiles, each banner advertisement profile including second values, the second values being values of the psychographic parameters, the second values indicating personality traits of users likely to be interested in the corresponding banner advertisement;

matching the user profile to the banner advertisement profiles to select the banner advertisement profile having the second values closest to the first values; and serving the banner advertisement corresponding to the matching banner profile.

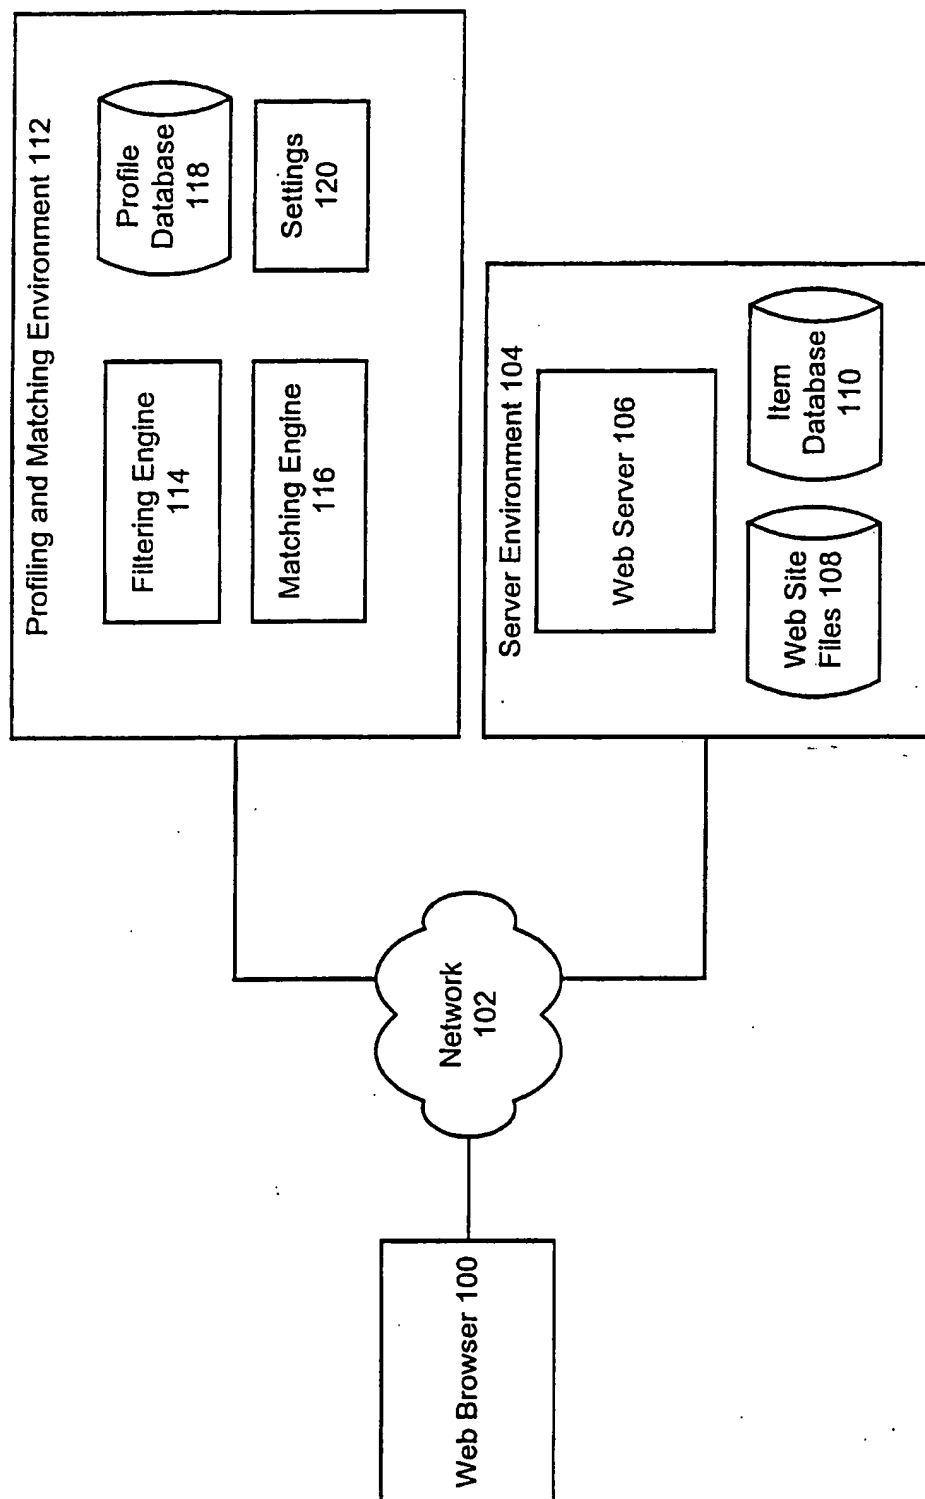

57. The method of claim 56 wherein the psychographic parameters include fields corresponding to at least the following personality types: sex (male or female), materialistic or non-materialistic, cost conscious or extravagant, socially liberal or socially conservative, libidinous or asexual, and technical or non-technical.

58. The method of claim 56 wherein serving the banner advertisement includes transmitting the banner advertisement to the internet, to be sent to the initiator of the banner advertisement request.

59. A method of sorting a list of items according to a user's likely interest using a computer system, the computer system including a user specific psychographic parameter values indicating psychographic traits for the user, the computer system further including a set of item specific psychographic parameter values for the items in the list, each of the set of item specific psychographic parameter values corresponding to an item and indicating psychographic traits of users interested in the corresponding item, the method comprising:
- responsive to receiving interaction data, the interaction data corresponding to events from which psychographic information can be obtained for the user, updating the user specific psychographic parameter values and the set of item specific psychographic parameter values; and
 - responsive to receiving the request to find an item, performing the following,
 - accessing the user specific psychographic parameter values,
 - accessing the set of item specific psychographic parameter values,
 - and
 - sorting the list of items, the priority of the items being selected based upon the proximity of the corresponding item specific psychographic parameter values to the user specific psychographic parameter values.
60. A method of receiving explicit feedback from a user regarding the user's interest in an item, the computer system including a user specific psychographic parameter values indicating psychographic traits for the user, the computer system further including a set of item specific psychographic parameter values, each of the set of item specific psychographic parameter values corresponding to an item and indicating psychographic traits of users interested in the corresponding item, the method comprising:
- receiving data from a user specified interest indicator about the item, the user specified interest indicator allowing a user to gauge his/her

interest in the item, the data being such that psychographic information can be obtained for the user; and updating the user specific psychographic parameter values and the set of item specific psychographic parameter values.

- 5 61. The method of claim 60 further comprising transmitting program code to the user, the program code to generate the user specified interest indicator.
62. The method of claim 60 further comprising transmitting program code to the user, the program code to generate the user specified interest indicator, wherein the user specified interest indicator corresponds to a sliding bar and
10 wherein the data corresponds to a number set by the user using the slider.
63. The method of claim 60 further comprising transmitting item information and program code to the user, the item information corresponding to a banner advertisement, and the program code to generate the user specified interest indicator over the banner advertisement.

INTERNATIONAL SEARCH REPORT

International application No.

PCT/US99/26783

A. CLASSIFICATION OF SUBJECT MATTER

IPC(7) : G06F 13/14, 17/60; H04M 3/56

US CL : 709/203, 217, 219

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 709/203, 217, 219

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X,E	US 6,009,410 A (LEMOLE ET AL.) 28 DECEMBER 1999, col.1-7	1-63
A, P	US 5,922,045 A (HANSON) 13 JULY 1999, col.2-6	1-63
A, P	US 5,894,554 A (LOWERY ET AL.) 13 APRIL 1999, col.2-8	1-63

☐ Further documents are listed in the continuation of Box C.
 ☐ See patent family annex.

* Special categories of cited documents:	*T later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
*A document defining the general state of the art which is not considered to be of particular relevance	*X document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
*B earlier document published on or after the international filing date	*Y document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
*L document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)	*A document member of the same patent family
*O document referring to an oral disclosure, use, exhibition or other means	
*P document published prior to the international filing date but later than the priority date claimed	

Date of the actual completion of the international search
